

Counting carbon and recreation lifts forests from \$115B to between \$240B and \$641B a year

Cumulative scenarios. Dots are central values, bars are low to high assumptions. These are not all GDP and should not be read as a national account.

Base: BEA wood and paper manufacturing net value added (value added less current-cost depreciation), 2022. Multipliers are applied to the net base, an approximation.
Multipliers: 5th percentile of state value-added multipliers (1.53), state median (1.83) and national (2.78), Arkansas Center for Forest Business (2023).
Carbon: net flux of forest land remaining forest land, 771.7 MMT CO₂e in 2022 (EPA Inventory 2024), valued at \$51 (Interagency Working Group 2021, 3%), \$120 and \$190 per tonne (EPA 2023, 2.5% and 2%), 2020 dollars.
No federal social cost of carbon has been in force since Executive Order 14154 (January 2025). Recreation: low is BEA hunting, shooting and trapping plus snow activities (\$24B, 2024); central and high assume 10% and 25% of BEA outdoor recreation value added (\$697B, 2024) occurs in forests, an assumption, not an estimate. Water supply and quality are excluded because no current national dollar value was verified.
Gray band: farm net value added less direct agricultural emissions (9.4% of 6,343 MMT CO₂e, EPA, 2022) at the same carbon prices, a scenario. Farms would also carry multipliers; nutrient and water damages are not counted for either sector. Forest products manufacturing emissions are not netted. Chart: Weiskittel and Daigneault, University of Maine.
