

On the books the forest sector is a quarter the size of agriculture. Count each sector's own carbon and it is about half (37% to 78%)

United States, 2022, \$B. Each sector is primary production plus first stage manufacturing.
Dots are central values at \$120 per t CO₂e, bars span \$51 to \$190 per t.

Forest sector: wood and paper manufacturing (BEA 3210, 3220). Agriculture sector: farms plus food, beverage and tobacco manufacturing (BEA 110C, 3110, 3120). Marine sector: BEA marine living resources (harvest, markets, processing, marine pharmaceuticals, fish based feeds). Forestry and logging and agricultural support services are excluded from both land sectors because BEA reports them in one combined line (113F). Net value added subtracts BEA current-cost depreciation of private nonresidential fixed assets by detailed industry (September 30, 2026), which BEA rates below its published aggregates in quality; subsidies are already netted out of value added. Marine depreciation is a proxy at the 113F and food manufacturing ratios. Carbon: forest land remaining forest land, net removal of 771.7 MMT CO₂e (EPA GHGI 2024); direct agriculture emissions 596 MMT (9.4% of 6,343 MMT, EPA, 2022); priced at \$51 (IWG 2021, 3%), \$120 and \$190 per t (EPA 2023, 2.5% and 2%), 2020 dollars; no federal value has been in force since January 2025. Not netted for any sector: mill, food plant and fishing fleet emissions, nutrient and water damages, and non-market benefits other than carbon (water, recreation). Scenarios on a common basis, not a national account. Chart: Weiskittel and Daigneault, University of Maine.
